

Project Title

Food Delivery Business Analysis Using Advanced MySQL Techniques

Introduction

The food delivery industry generates large volumes of transactional data, including customer orders, restaurant information, cuisine types, and promotional activities. Analyzing this data enables businesses to better understand customer behavior, evaluate restaurant performance, and make informed business decisions.

This project uses Advanced MySQL techniques to analyze food delivery order data and solve real-world business problems. The analysis focuses on customer acquisition, customer retention, promotional campaign effectiveness, and restaurant performance, providing valuable insights to support data-driven business decisions.

Business Problem

The food delivery company wants to gain deeper insights into customer behavior and restaurant performance using historical order data.

The objective is to identify high-performing restaurants, monitor customer acquisition trends, analyze promotional campaign effectiveness, identify inactive customers for re-engagement, and understand customer purchasing patterns. Advanced MySQL techniques are used to answer key business questions and transform raw transactional data into actionable business insights.

Database Information

Database: `food_delivery`

Main Table: `orders`

The dataset contains order-level information, including:

- `order_id`
- `Customer_code`
- `Placed_at`
- `Restaurant_id`

- Cuisine
 - Order_status
 - Promo_code_name
-

Business Questions

Task 1: Top 3 Outlets by Cuisine Type

The business wants to identify the top three restaurants within each cuisine category based on the total number of orders received.

The analysis will rank restaurants within each cuisine category without using the `LIMIT` clause or any TOP function.

Task 2: Daily New Customer Acquisition

The business wants to monitor customer acquisition from the launch date by calculating the number of new customers acquired each day.

The analysis will identify each customer's first order date and calculate the daily count of newly acquired customers.

Task 3: Customers Acquired in January 2025 Who Ordered Only Once

The business wants to identify customers who:

- Were acquired in January 2025.
- Placed only one order during January 2025.
- Did not place any additional orders before or after January 2025.

This analysis helps identify one-time customers who did not return after their first purchase.

Task 4: Inactive Customers with Promotional First Orders

The business wants to identify customers who:

- Were acquired more than one month ago.
- Have not placed any orders in the last seven days.
- Used a promotional code on their first order.

These customers can be targeted through personalized re-engagement campaigns.

Task 5: Trigger Customers After Every Third Order

The Growth Team wants to create an automated trigger that sends personalized communication after every third customer order.

The analysis identifies customers immediately after completing their:

- 3rd Order
- 6th Order
- 9th Order
- Every subsequent multiple of three

This supports loyalty programs and personalized customer engagement.

Task 6: Customers Who Used Promotional Codes on Every Order

The business wants to identify customers who:

- Have placed more than one order.
- Used a promotional code on every order they placed.

This analysis helps evaluate customer dependency on promotional offers.

Task 7: Organic Customer Acquisition in January 2025

The business wants to calculate the percentage of customers acquired during January 2025 whose first order was placed without using a promotional code.

This analysis measures the contribution of organic customer acquisition compared with promotion-driven acquisition.
